

# Projected Shortage at Givhans Ferry

Sept 2021

# BACKGROUND

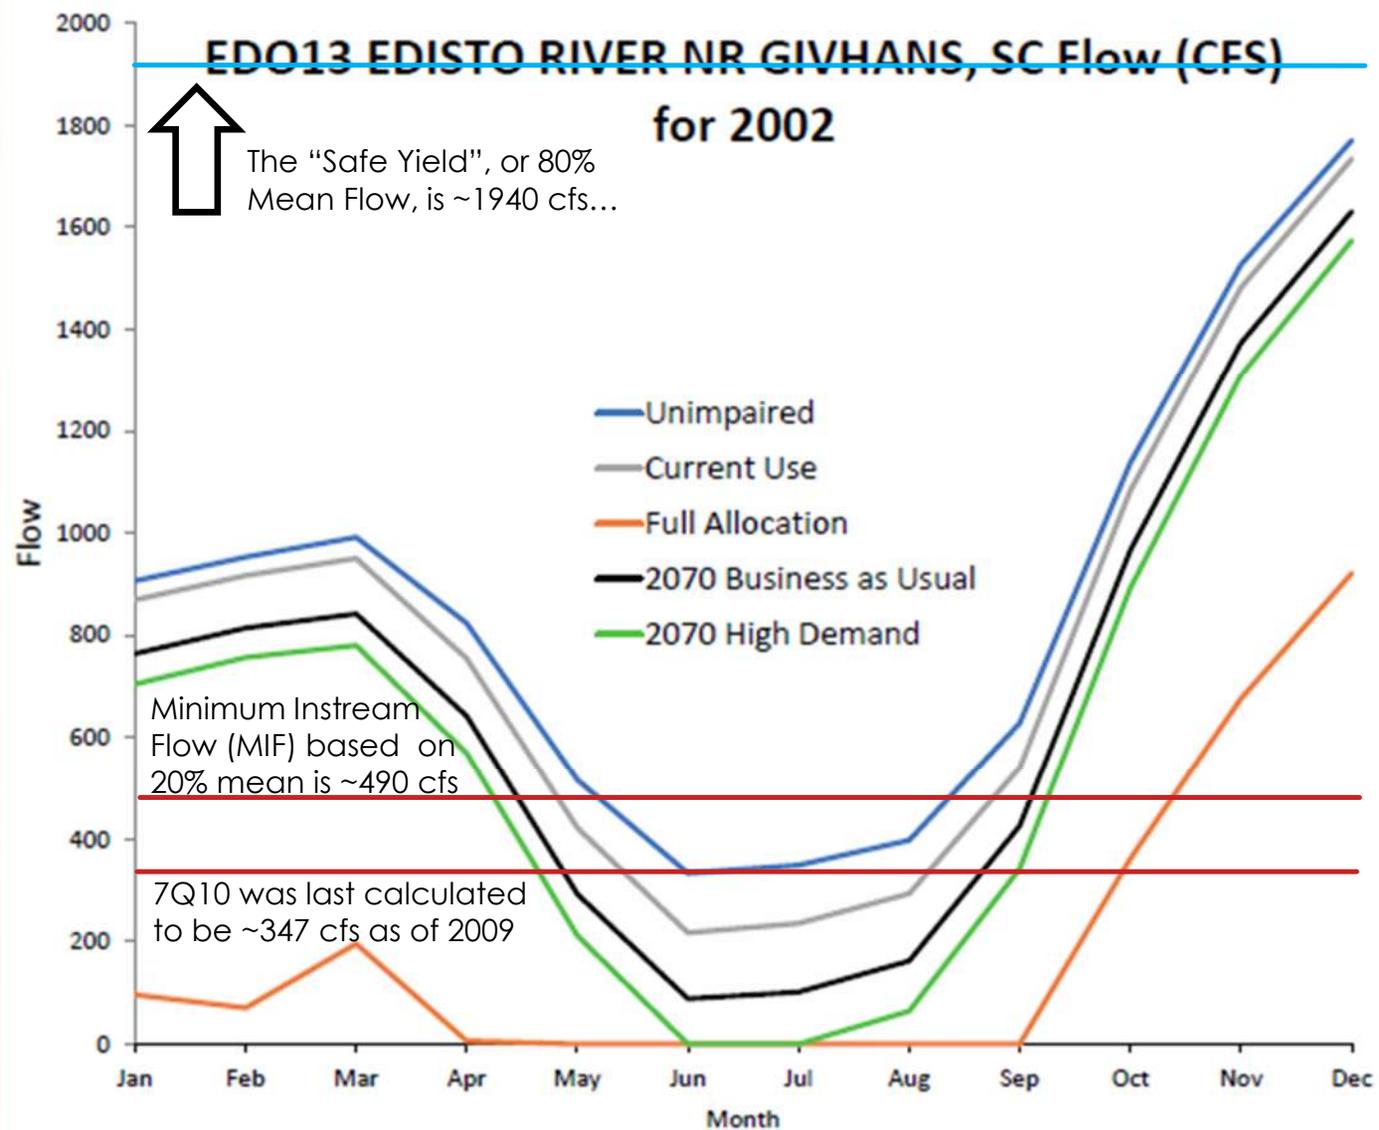

- ▶ CWS has been aware of the decreasing flows at Givhans Ferry over the past few decades despite our using less Edisto than we did in the 1990's
  - ▶ The modeled results confirm this has been the case and is likely to get worse over the coming decades
  - ▶ This is why it is so important that we develop a river basin plan all of the RBC stakeholders can get behind
- 

# OUTLINE

- ▶ Is there a reach of interest (or even shortage) at Givhans?
  - ▶ Should a surface water condition be identified?
  - ▶ What management strategy or strategies should we consider?
- 

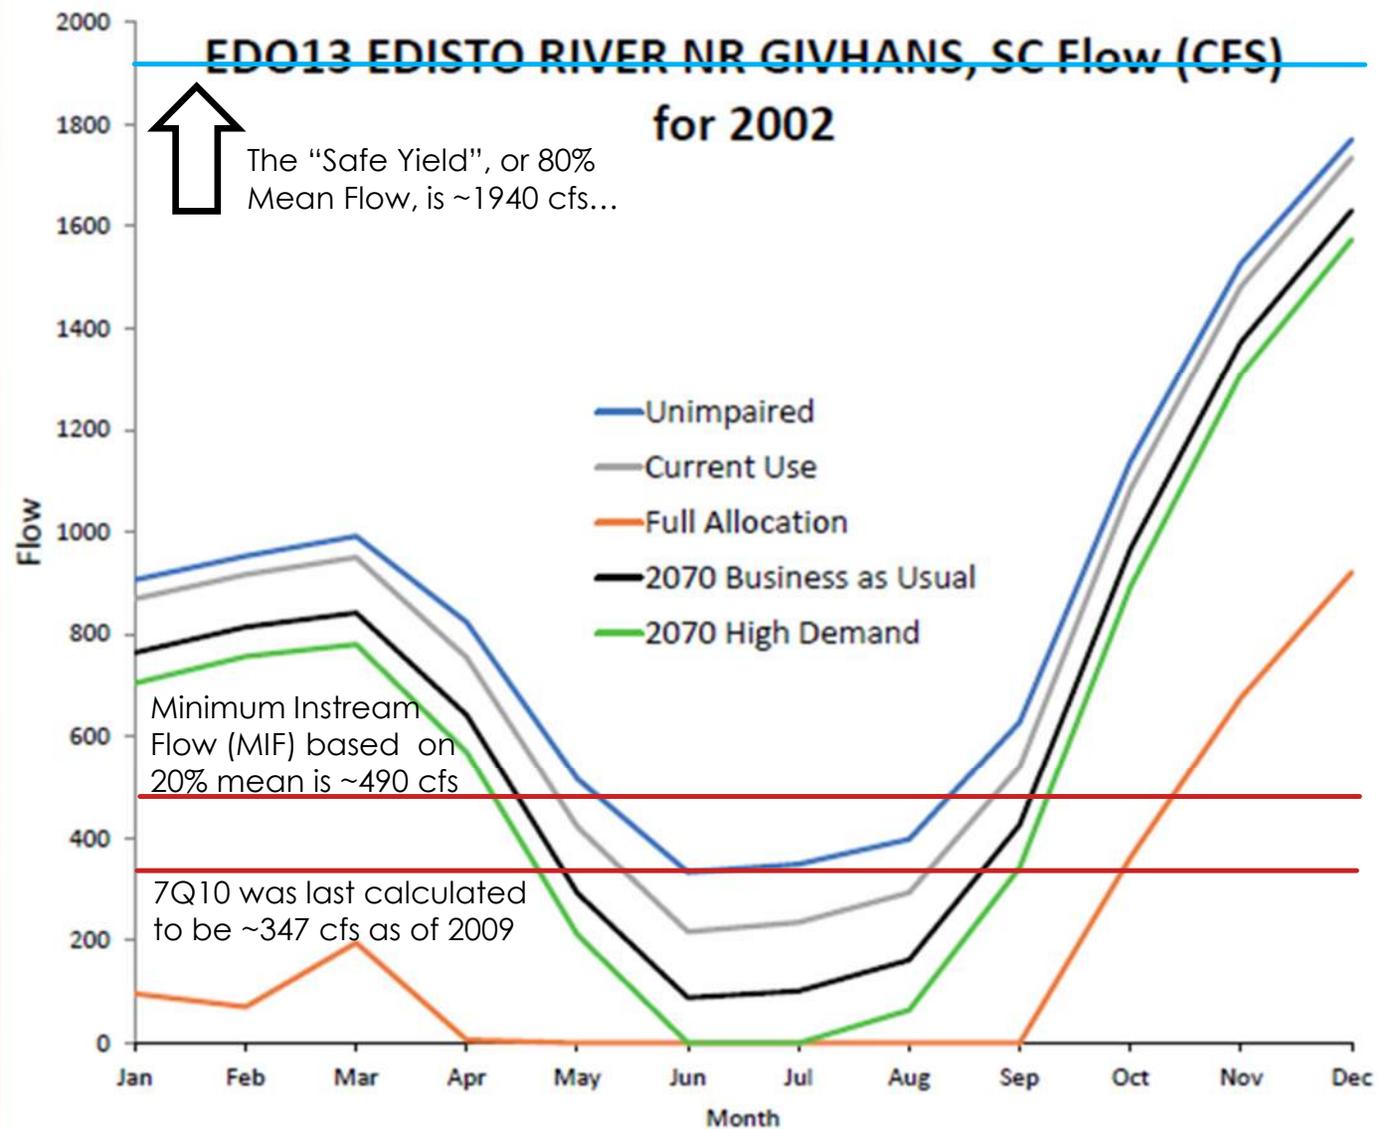

# IS THERE A PROJECTED SHORTAGE

- ▶ The “unimpaired” scenario shows flows under MIF even with no withdrawal
- ▶ The “current use” scenario shows flows have already been low during drought
- ▶ Obviously increased withdrawals will lead to even lower flows

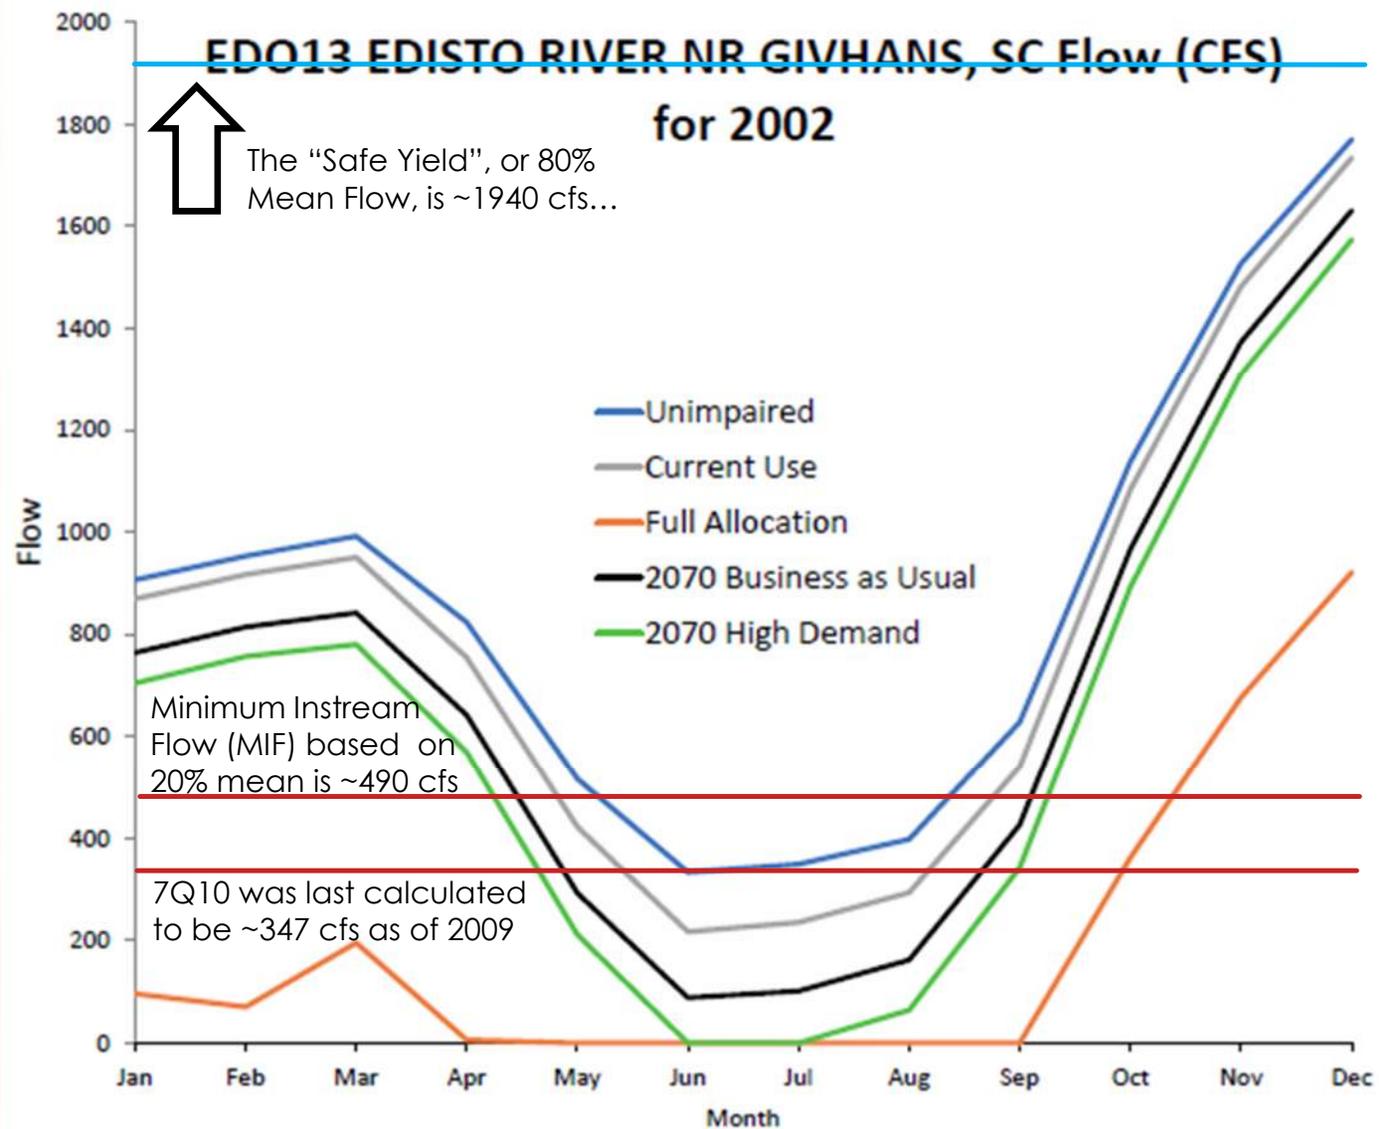

# IS THERE A PROJECTED SHORTAGE

- ▶ Much lower flows are likely to result even in the “business-as-usual” scenario
- ▶ The river is projected to reach zero flow by 2070 in both the “high demand” and “full-allocation” scenarios

# IS THERE A PROJECTED SHORTAGE

- ▶ The results of all of the scenarios point to the fact the resource has likely been fully allocated even if you don't include the recent registrations

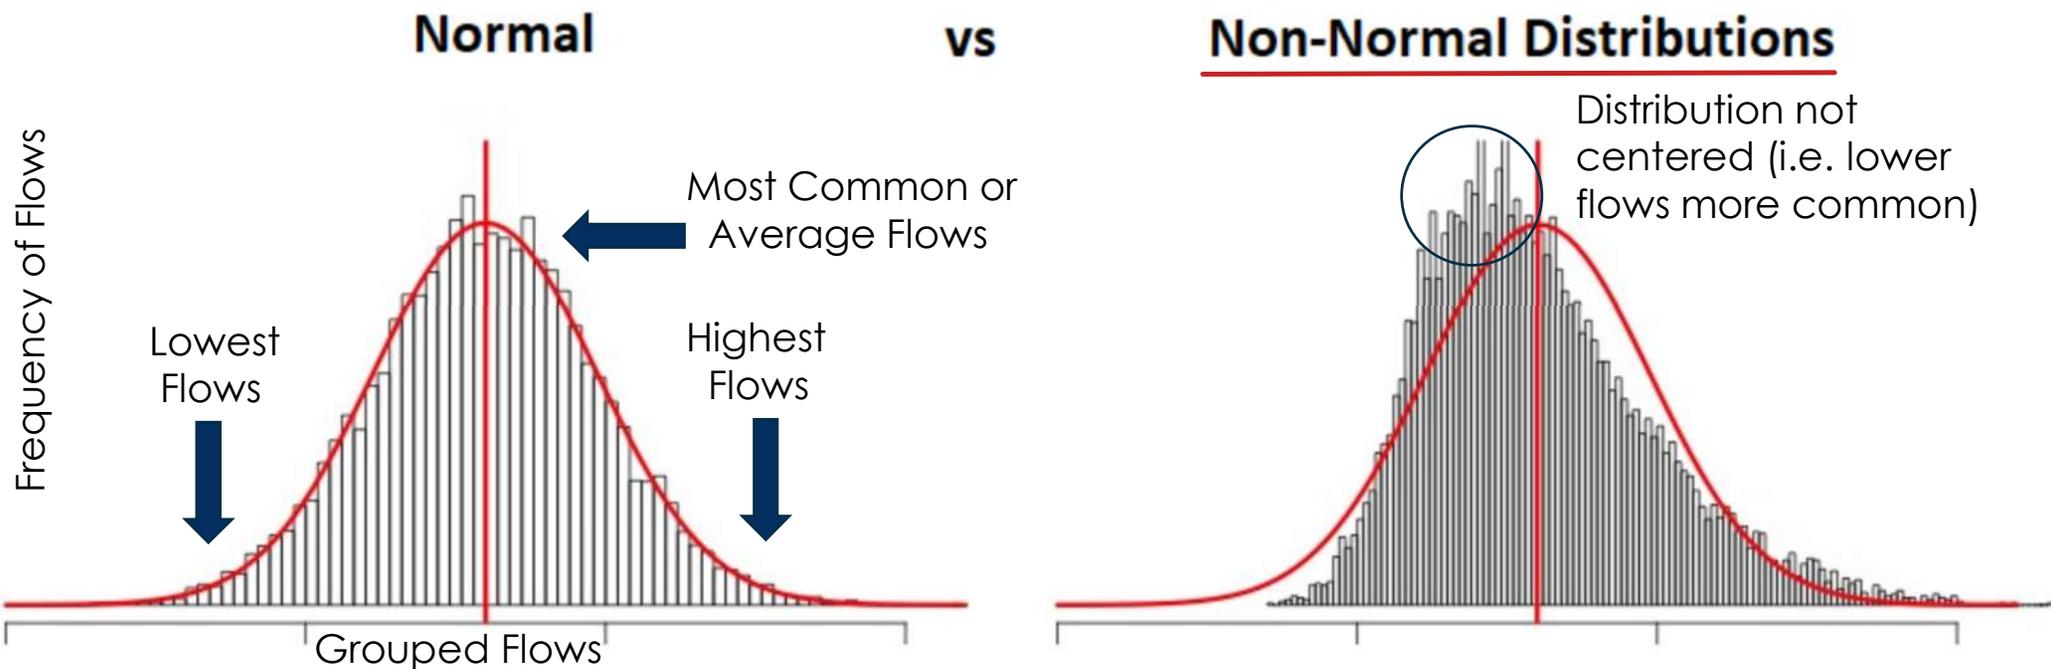

## SHOULD ANY SURFACE WATER CONDITION BE IDENTIFIED

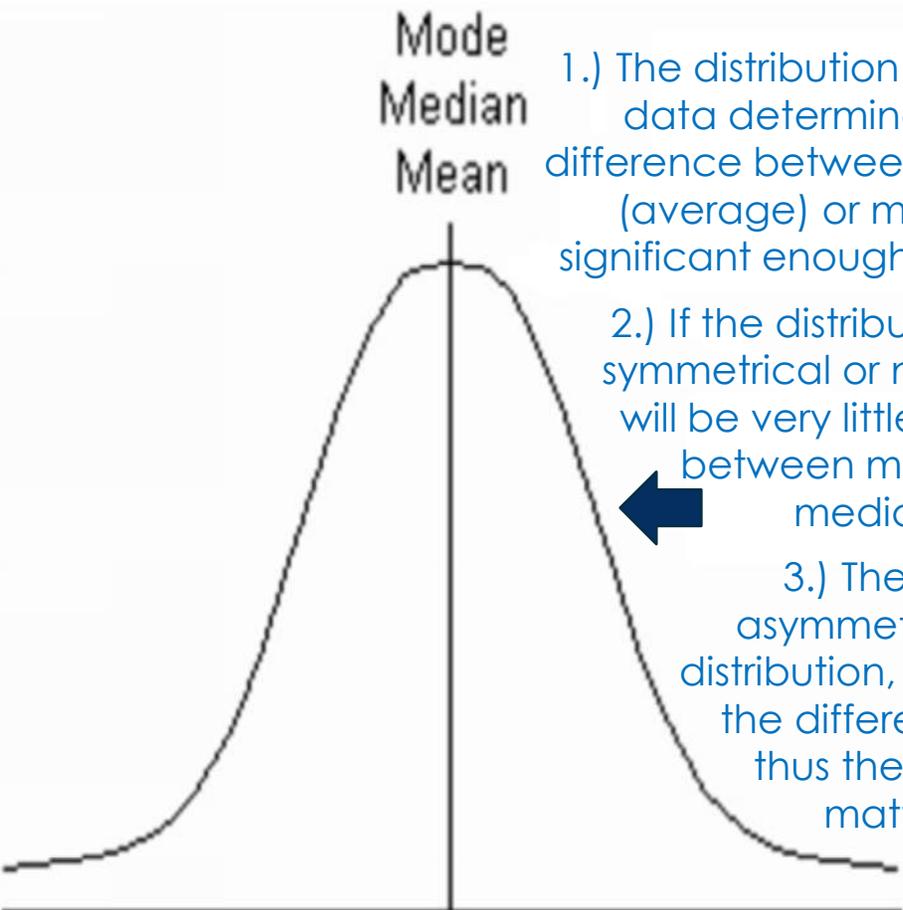

- ▶ Yes, because in the absence of a “surface water condition”, a “surface water shortage” isn’t recognized until there is no streamflow left
- ▶ A surface water condition is needed to:
  - ▶ ensure the river basin plan acknowledges when the water resources are strained long before the river runs dry
  - ▶ trigger action before the last user runs out of water or the river runs dry
- ▶ Even during drought, the last withdrawer:
  - ▶ should have some portion of their allocation
  - ▶ shouldn’t be put in the position of having to decide if they can leave any water for the environment

# WHAT SHOULD THE SURFACE WATER CONDITION BE BASED ON OR BE IN REFERENCE TO

- ▶ Water quantity standards have historically referenced mean (average)
- ▶ A surface condition is different than a water quantity standard
- ▶ But should a surface condition at Givhans be based on mean flow or something else, like median flow?
- ▶ Why mean or median matters?

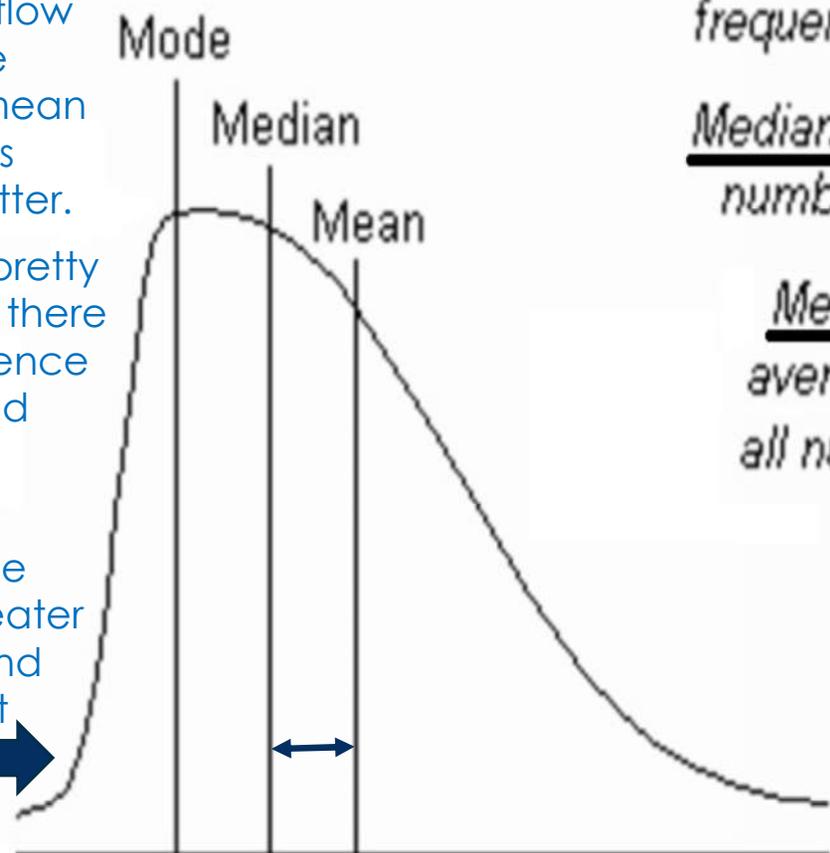

# Histograms: Grouping Streamflow Data into Distributions

symmetrical distribution  
Normal Distribution

- 1.) The distribution of the flow data determines if the difference between the mean (average) or median is significant enough to matter.
- 2.) If the distribution is pretty symmetrical or normal, there will be very little difference between mean and median! ←
- 3.) The more asymmetrical the distribution, the greater the difference and thus the more it matters. →

asymmetrical distribution  
non-Normal Distribution

Mode is most frequent number

Median is middle number in list

Mean is average of all numbers

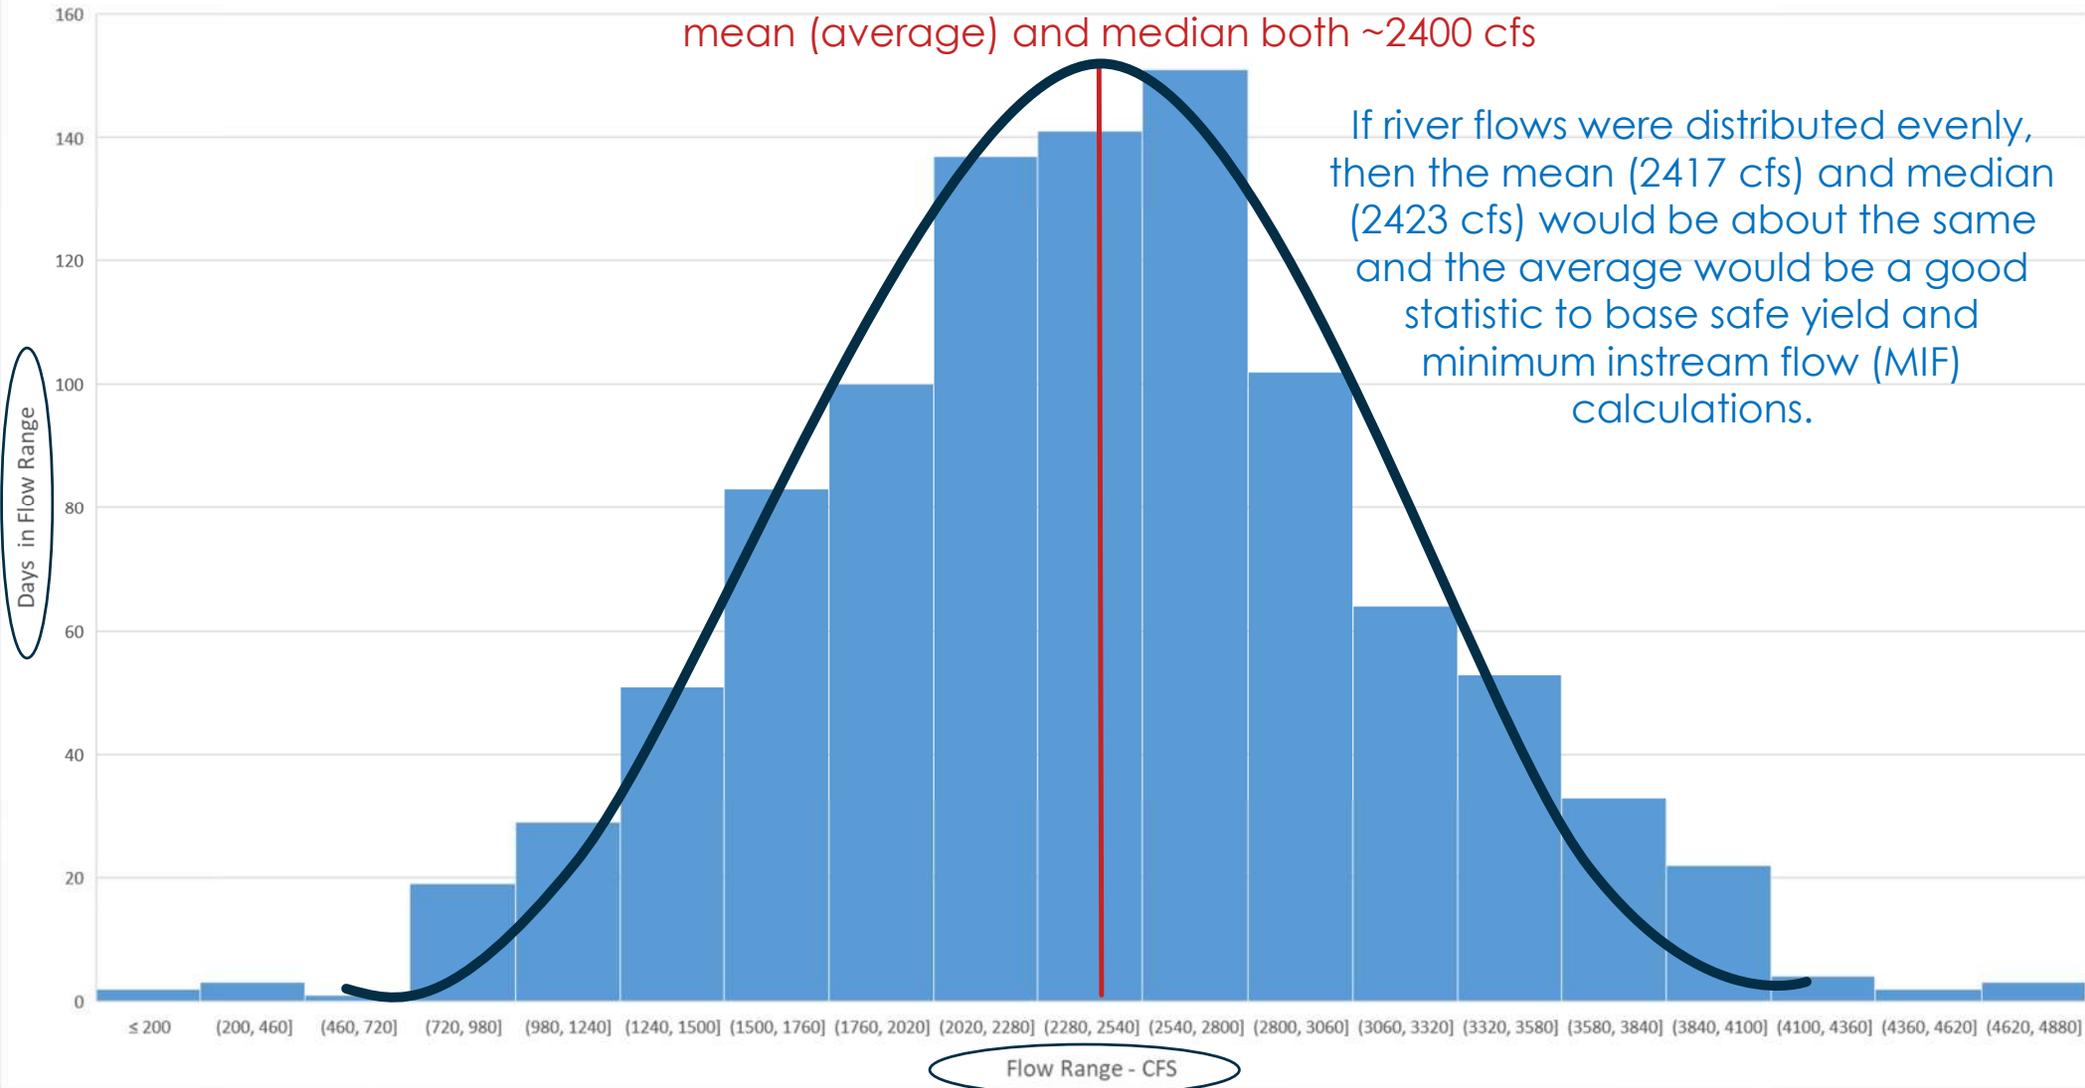

vs

### Normal Distribution - Hypothetical Data Set

n = 1000

mean (average) and median both ~2400 cfs

If river flows were distributed evenly, then the mean (2417 cfs) and median (2423 cfs) would be about the same and the average would be a good statistic to base safe yield and minimum instream flow (MIF) calculations.

### 81 Years at Givhans Ferry - Histogram

n = 29806

### Actual non-Normal Flow Distribution at Givhans

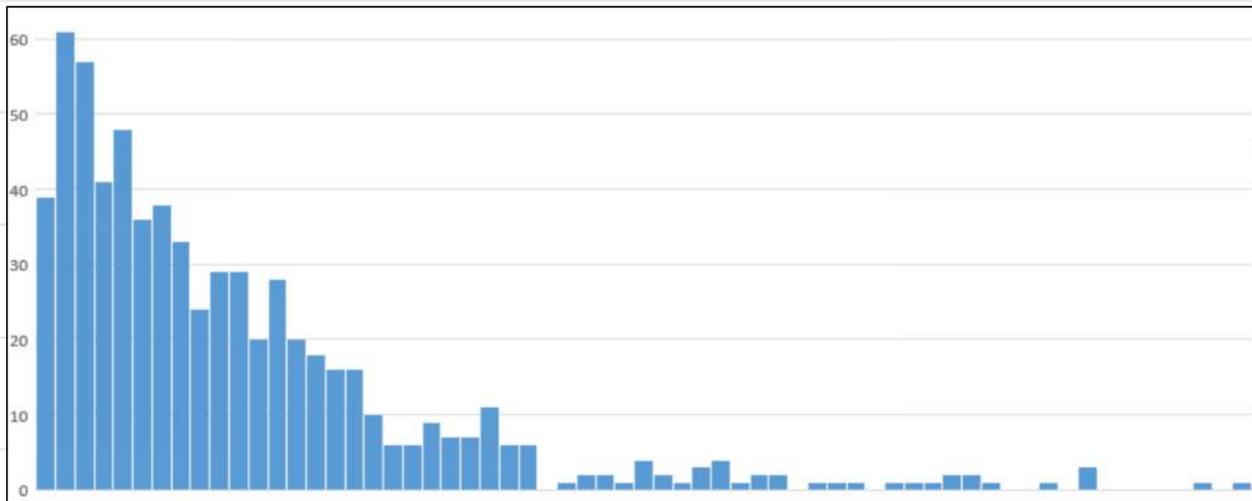

Does **mean** or **median** represent a more “typical” river flow?

Median does since the data is non-normal. Using mean flow from a non-normal data set will always result in a safe yield and minimum instream flow calculations that over estimates water availability.

Mode ~673 to 935 cfs

Median ~1700 cfs median

Mean (Average) ~2400 cfs

10000 cfs → 26000 cfs

# MEAN VS MEDIAN

- ▶ Choosing to use median rather than mean (average) doesn't ignore the highest flood flows
- ▶ No data is being removed
- ▶ Using the median just doesn't let the drastically high flood flows carry as much weight as they do when using mean (average) to determine the most appropriate:
  - ▶ Safe Yield
  - ▶ MIF
  - ▶ Surface Condition
  - ▶ Etc.

# SURFACE CONDITIONS

- ▶ Mean probably isn't the best statistic to determine or reference a surface condition
- ▶ Median is one option, but there are also others like:
  - ▶ Percentile (used by USGS)
  - ▶ 7Q10 (referenced in USGS studies, the Drought Response Act and CWS's contingency plan)
- ▶ At what flow should our river basin plan acknowledge a water shortage exists? Zero or something else?
- ▶ And what should we do when the river gets that low

# MANAGEMENT STRATEGY

- ▶ Low flows at Givhans Ferry during drought are the result of a combination of basin-wide conditions:
  - ~~Lack of precipitation~~
  - ~~Increased evapotranspiration~~
  - ~~Reduced inflow due to lower ground water levels~~
  - Increased withdrawals
- ▶ Less important than asking which of these is this biggest problem is the question: Which of the above do we have any ability to affect?

# MANAGEMENT STRATEGIES

- ▶ Generally two Types of management strategies or Best Management Practices (BMPs)
- ▶ **Resource stretching** (i.e. low flow toilets, crop irrigation nozzle BMPs, etc.) vs “**what if**” this or that happens...
- ▶ Our River Basin Plan needs both types if it is to be meaningful and comprehensive
- ▶ But I believe the latter “what if” type of strategy is needed to address low flows during drought
- ▶ And it isn’t as much a matter of “what if” but “when”

# A SURFACE CONDITION AND LOW FLOW MANAGEMENT STRATEGY GO HAND-IN-HAND

- ▶ Since a surface condition may be closely tied to a low flow management strategy, it makes sense to develop and agree to them at the same time
  - ▶ I have some ideas, but I believe the other surface withdrawers need to weigh in and have an equal voice on the details especially as those details may in some cases be site specific
  - ▶ I propose that we create a subcommittee of at least the surface withdrawers (Water, Agriculture and Power) to work on the details of a proposed surface condition and low flow management strategy
- 

## WITHDRAWAL GROUPS SUBCOMMITTEE

- ▶ The goal is to create an environment conducive to making progress on answering the question how can we minimize the impacts of drought
  - ▶ The subcommittee will present the recommendations to the RBC for further discussion and a possible vote
  - ▶ This will also set the stage to begin more conversations around the resource stretching management strategies
-
